

Socket programming

goal: learn how to build client/server applications that communicate using sockets

socket: door between application process and end-end-transport protocol

Socket programming

Two socket types for two transport services:

- **UDP:** unreliable datagram
- **TCP:** reliable, byte stream-oriented

Application Example:

1. Client reads a line of characters (data) from its keyboard and sends the data to the server.
2. The server receives the data and converts characters to uppercase.
3. The server sends the modified data to the client.
4. The client receives the modified data and displays the line on its screen.

Socket programming *with UDP*

UDP: no “connection” between client & server

- no handshaking before sending data
- sender explicitly attaches IP destination address and port # to each packet
- rcvr extracts sender IP address and port# from received packet

UDP: transmitted data may be lost or received out-of-order

Application viewpoint:

- UDP provides *unreliable* transfer of groups of bytes (“datagrams”) between client and server

Client/server socket interaction: UDP

server (running on serverIP)

create socket, port= x:
`serverSocket =
socket(AF_INET,SOCK_DGRAM)`

↓
read datagram from
`serverSocket`

↓
write reply to
`serverSocket`
specifying
client address,
port number

client

create socket:
`clientSocket =
socket(AF_INET,SOCK_DGRAM)`

↓
Create datagram with server IP and
port=x; send datagram via
`clientSocket`

↓
read datagram from
`clientSocket`

↓
close
`clientSocket`

Example app: UDP client

Python UDPClient

include Python's socket library	→	from socket import *
		serverName = 'hostname'
		serverPort = 12000
create UDP socket for server	→	clientSocket = socket(socket.AF_INET, socket.SOCK_DGRAM)
get user keyboard input	→	message = raw_input('Input lowercase sentence:') clientSocket.sendto(message,(serverName, serverPort))
Attach server name, port to message; send into socket	→	modifiedMessage, serverAddress = clientSocket.recvfrom(2048)
read reply characters from socket into string	→	print modifiedMessage
print out received string and close socket	→	clientSocket.close()

Example app: UDP server

Python UDPServer

```
from socket import *
serverPort = 12000
serverSocket = socket(AF_INET, SOCK_DGRAM)
serverSocket.bind(('', serverPort))
print "The server is ready to receive"
while 1:
    message, clientAddress = serverSocket.recvfrom(2048)
    modifiedMessage = message.upper()
    serverSocket.sendto(modifiedMessage, clientAddress)
```

create UDP socket →

bind socket to local port
number 12000 →

loop forever →

Read from UDP socket into
message, getting client's
address (client IP and port) →

send upper case string
back to this client →

Socket programming *with TCP*

client must contact server

- server process must first be running
- server must have created socket (door) that welcomes client's contact

client contacts server by:

- Creating TCP socket, specifying IP address, port number of server process
- *when client creates socket:* client TCP establishes connection to server TCP

- when contacted by client, *server TCP creates new socket* for server process to communicate with that particular client
 - allows server to talk with multiple clients
 - source port numbers used to distinguish clients (more in Chap 3)

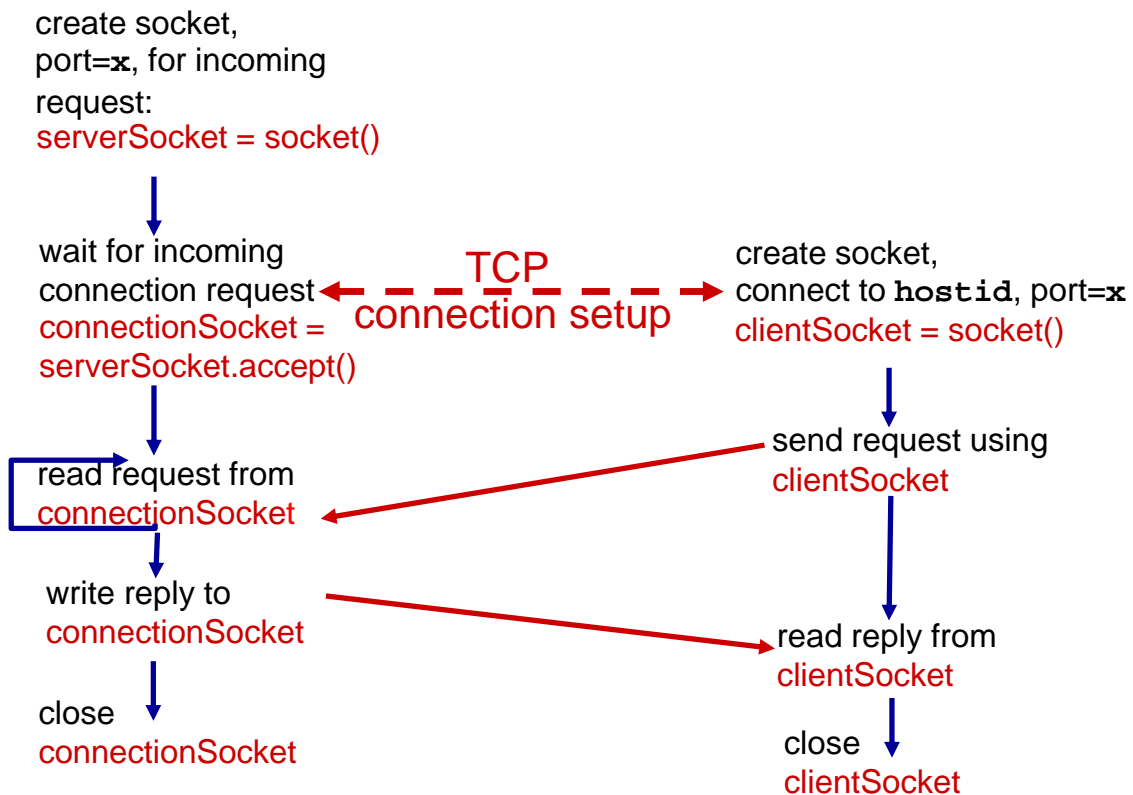

application viewpoint:

TCP provides reliable, in-order byte-stream transfer (“pipe”) between client and server

Client/server socket interaction:TCP

server (running on `hostid`)

client

Example app: TCP client

Python TCPClient

create TCP socket for
server, remote port 12000

```
from socket import *
serverName = 'servername'
serverPort = 12000
clientSocket = socket(AF_INET, SOCK_STREAM)
clientSocket.connect((serverName, serverPort))
sentence = raw_input('Input lowercase sentence:')
clientSocket.send(sentence)
modifiedSentence = clientSocket.recv(1024)
print 'From Server:', modifiedSentence
clientSocket.close()
```

No need to attach server
name, port

Example app: TCP server

Python TCPServer

create TCP welcoming socket	→	from socket import *
		serverPort = 12000
		serverSocket = socket(AF_INET, SOCK_STREAM)
		serverSocket.bind(('', serverPort))
server begins listening for incoming TCP requests	→	serverSocket.listen(1)
		print 'The server is ready to receive'
		while 1:
loop forever	→	connectionSocket, addr = serverSocket.accept()
server waits on accept() for incoming requests, new socket created on return	→	sentence = connectionSocket.recv(1024)
		capitalizedSentence = sentence.upper()
read bytes from socket (but not address as in UDP)	→	connectionSocket.send(capitalizedSentence)
		connectionSocket.close()
close connection to this client (but <i>not</i> welcoming socket)	→	

Chapter 2: summary

our study of network apps now complete!

- application architectures
 - client-server
 - P2P
- application service requirements:
 - reliability, bandwidth, delay
- Internet transport service model
 - connection-oriented, reliable: TCP
 - unreliable, datagrams: UDP
- ❖ specific protocols:
 - HTTP
 - FTP
 - SMTP, POP, IMAP
 - DNS
 - P2P: BitTorrent, DHT
- ❖ socket programming: TCP, UDP sockets

Chapter 2: summary

most importantly: learned about protocols!

- typical request/reply message exchange:
 - client requests info or service
 - server responds with data, status code
- message formats:
 - headers: fields giving info about data
 - data: info being communicated

important themes:

- ❖ control vs. data msgs
 - in-band, out-of-band
- ❖ centralized vs. decentralized
- ❖ stateless vs. stateful
- ❖ reliable vs. unreliable msg transfer
- ❖ “complexity at network edge”
